

MORPHOLOGICAL DISAMBIGUATION**ABSTRACT**

A method for morphological disambiguation includes receiving an input string and morphologically analyzing the string to generate a list of candidate analyses of the string, each candidate analysis including a respective word and a linguistic pattern of the word. The pattern of each of the analyses is evaluated against a predefined criterion in order to select one or more of the analyses from the list. The method is suitable particularly for computerized analysis and searching in Hebrew and other Semitic languages.
